16. Abstract

This document was prepared under the supervision of the Office of Aviation Policy and Plans of the Federal Aviation Administration (FAA). It provides technical documentation for the FAA's report, "Airport and Airway Costs: Allocation and Recovery in the 1980s," (FAA-APO-87-7).

This volume provides detailed information on the estimation of econometric cost functions for certain FAA operating sites. These functions relate costs to measures of service provided such as operations handled and pilot briefs prepared. A separate cost function is estimated for each type of FAA site--Air Route Traffic Control Centers, Flight Service Stations, Terminal Radar Approach Controls, and VFR towers--for both 1984 and 1992.

SECTION 1.0

INTRODUCTION

This volume provides detailed information on the estimation of econometric cost functions for FAA operating sites--ARTCCs, FSSs, TRACONs and towers. For each type of operating site, two cost functions were estimated--one for 1984 and one for 1992. Results of these econometric analysis have been reported in Volumes 1 and 2, together with their use in the cost allocation process. This volume focuses exclusively on econometric issues.

There are a number of conceptual issues that need to be addressed before proceeding to the econometric results. These issues are related to the following topics:

- Resource and budget costs,
- Sunk costs,
- Joint and separable production functions,
- Direct costs,
- Indirect costs,
- Measures of activity,
- Joint cost functions.

These issues are addressed in the present section immediately below. Thereafter, the results for each type of operating site are reported in Section 2.0. Databases utilized to develop these estimates are included as an appendix in this volume.

1.1 Resource and Budget Costs

An appropriate measure of the avoidable resource cost is the value that society places on those goods and services not produced as the result of resources being diverted to the production of ATC services. The conceptually correct valuation of these costs requires the identification of society's willingness-to-pay for these foregone consumption opportunities.

If all resource markets are competitive, and the FAA is charged competitive market prices for all inputs to the production of ATC services, then resource and budget costs (i.e., the costs that appear in FAA budgets) will exactly coincide. These costs, however, may differ if resource markets are not competitive, or if the inputs purchased by the FAA are subsidized.

In the analyses that follow, it is assumed that resource markets are competitive in the long run--i.e., private sector providers of inputs to the FAA do not earn long run economic profits. This assumption is consistent with the main objective of this study--namely, to allocate the current and projected FAA budgets among user groups.

1.2 Sunk Costs

Sunk costs are those costs that are associated with the use of a resource that has already been purchased, and has no alternative use. For example, the cost associated with the purchase of equipment that has no alternative use outside the FSS system (i.e., the equipment cannot be resold on the market) are

sunk. Sunk costs are not avoidable either in the short run or the long run.

In the present study, existing FAA capital is assumed to be sunk. No return to this capital is imputed. In Appendix A of Volume 2, there is an extensive discussion of the reasons for this assumption. Here, it is appropriate to note that with a few notable exceptions, most ATC capital probably is truly sunk.

1.3 Joint and Separable Production Costs

The cost analysis of the ATC system is complicated by the fact that operating sites produce many services jointly and also provide these services to multiple types of users. A cost is separable if it can be traced directly to the provision of a specific service to a specific user group. Separable costs are avoidable; that is, separable costs vanish if the service to which they are attributed is no longer produced.

Joint costs are those costs that are incurred as the result of the production of more than one service. In general, joint costs will not disappear if an operating site is relieved of the responsibility of producing any given single service or of providing service to a user group. Joint or non-separable costs are avoidable only if no services are produced by the facilities.

1.4 Direct FAA Costs Exclusive of Capital Costs

Direct FAA costs exclusive of capital costs are likely to represent the largest component of avoidable costs at FAA operating sites. Consequently, considerable attention is focused on the analysis of these costs.

The principal components of direct ATC non-capital costs include the following:

- o Air traffic staffing costs,
- o Airway facilities staffing costs,
- o Leased communications costs.

The databases that were used in the analyses of both current and future (i.e., 1992) costs were constructed from these individual components of the FAA budget.

Air Traffic Staffing Costs--Air Traffic staffing costs represent the expenses for personnel directly responsible for the operation of ATC sites. These costs include the base salary of all personnel and a markup which accounts for other labor expenses. Specifically, the markup includes factors for fringe benefits, operational responsibility pay, premium pay, and overtime. Staffing levels for 1984 were provided by ATR 720. Future staffing levels were provided by the following:

- o ARTCC: based on staffing standards provided by ATR-720,
- o FSS: ATR-720,
- o Towers and TRACONs: AMS-560.

Current system labor rates were GS-Step 5 of the actual complement reported; in the future, these rates were increased by the assumed inflation rate.

Airway Facilities Staffing Costs--Airway Facilities staffing costs are the labor costs associated with the maintenance and upkeep of ATC facilities. The ATC system shares the Airways Facilities staff with other parts of the FAA; portions of the

expenses associated with the Airways Facilities staff are assigned to individual ATC facilities systems based on existing equipment at each site, and estimated annual labor hours (and therefore costs) of maintaining the equipment.

Staffing for 1984 was based on the Facilities Master File (FMF) database provided by APM-130. Hours were aggregated by major system for each site and then converted to employee-years. Labor costs (including supervision) were based on the average cost per AFS employee estimated from the maintenance portion of the 1984 budget.

The procedure for 1992 was a mirror image of the 1984 method except that labor hours were identified for the 1992 system from the forecast 1990 FMF.

Leased Communications Costs--Leased telecommunications costs are the expenses incurred by operating sites for leased communications equipment and services. These permit ATC personnel to communicate with both airmen and other facilities of the National Airspace System. Information on these costs was available from the FAAC's database only for 1984; estimates of future costs were unavailable, although the share of direct costs accounted for by this cost category is expected to decline.

1.5 Indirect ATC Costs

In addition to the direct costs associated with the operation and maintenance of operating facilities, there are also indirect costs associated with the ATC system. These indirect costs include administrative costs not assigned directly to any single facility. It is likely that some of these indirect

administrative costs would be reduced under the alternative privatization configurations. Estimates of these costs are reported in Volumes 1 and 2 and are not repeated here.

1.6 Measures of Activity

The FAA maintains records of traffic and service counts at all ATC facilities. These measures of output have been used in the econometric functions described below. More specifically, the measures are as follows:

- ARTCCs - handles
- FSSs - pilot briefs, IFR flight plans, VFR flight plans, and air contacts.[1]
- TRACONs - operations, seconds, and overs.
- Towers - operations.

Estimates of future services at each type of facility were derived from the following sources:

- ARTCCs - "Air Route Traffic Control Center Forecast--Fiscal Years 1985-1996" (April, 1985).
- FSSs - "Total Flight Services, Pilot Briefs, Aircraft Contacted and Flight Plans Originated--Flight Service Stations--Fiscal Years 1985-1992" (October, 1985).
- TRACONs and towers - "FAA Terminal Area Forecast" (1984).

It should be noted that the tower and TRACON output measures were derived from the terminal area forecast because "FAA Aviation Forecasts" does not provide a breakdown of relative growth rates at TRACONs and towers.

TRACON and tower data were modified using OAG data to identify commuter and international operations. The procedure is described in Appendix A.

1.7 Joint Cost Functions

A joint cost function expresses a relationship between costs and some measure of joint output or productivity. For example, let C_i and Q_i represent, respectively, total direct costs and a measure of joint output for the ith facility. The cost function can then be written:

$$C_i = f(Q_i)$$

If the cost function is known, the marginal cost of the jth service at the ith facility, $MC(Q_{ij})$ can be computed as:

$$MC(Q_{ij}) = \partial C_i / \partial Q_{ij}$$

where Q_{ij} is the output of the jth service at the ith facility.[2]

Given $MC(Q_{ij})$, the avoidable costs of producing the jth service at the ith facility, $V(Q_{ij})$, can be computed as:

$$V(Q_{ij}) = \int_0^{Q_{ij}} MC(Q_{ij})dQ_{ij}$$

The avoidable costs of producing the jth service for the entire system can be computed by summing $V(Q_{ij})$ over all facilities.

With these preliminary matters completed, the results are reported in Section 2.0.

SECTION 2.0

RESULTS

This section reports the results of the econometric cost functions estimated for FAA operating sites--ARTCCs, FSSs, TRACONs, and towers--for the years 1984 and 1992.

The results for 1984 are reported in 1984 dollars. The 1992 cost functions were estimated in 1986 dollars. A comparison of the results for the two years is shown in Table 2.1, which presents the results of both cost functions in terms of 1986 dollars. A full discussion of the implications of these results can be found in Section 2.0 of Volume 2. Here it need only be noted that future system costs are forecast to decline substantially. This is due to the improvements in productivity attributable to new capital equipment being installed under the National Airspace System Plan.[3]

In reaching these conclusions, several tests of the properties of the cost functions were conducted. Common for all types of facilities were tests for:

- Non-linearity,
- Differences in the cost of producing output for different user groups,
- Multicollinearity.

Each of these is briefly described below.

Table 2.1

COMPARISON OF 1984 AND 1992 OPERATING SITE COSTS

(1986 Dollars)

Marginal Costs	ARTCCs (Handles) 1984	ARTCCs (Handles) 1992	FSSs (Services) 1984	FSSs (Services) 1992	TRACONs (TSOs)* 1984	TRACONs (TSOs)* 1992	Towers (Operations) 1984	Towers (Operations) 1992
- Air Carrier	$14.42	$10.86	$6.69	$4.27	$13.25	$12.55	$8.19	$8.48
- Commuters	$14.42	$10.86	$6.69	$4.27	$13.25	$12.55	$1.93	$1.75
- General Aviation	$13.07	$10.86	$6.69	$4.27	$3.56	$4.72	$1.49	$1.16
- Military	$22.05	$17.29	$6.69	$4.27	$13.25	$12.55	$4.61	$3.05
Joint Costs Per Site	$4,225,062	$5,865,511	$93,066	$477,317	$880,073	$1,308,647	$400,155**	$519,151**
R-Squared	.896	.872	.929	.897	.867	.804	.555	.763

* TSO's equal operations, seconds and overs at TRACON's.

** Level 1 Tower joint costs are $85,133 lower in 1984 and $252,713 lower in 1992.

2.1 Non-Linearity

One of the key steps in estimating any economic function is testing for alternative functional forms. Under many circumstances, economic theory specifies those forms which are consistent with market expectations. For the present case, there are no theoretic reasons for expecting a particular functional form. As it turns out, linear functions were found for all four types of operating sites. However, log linear and quadratic forms were tested. In all cases, these forms were less satisfying than the linear forms. Furthermore, visual inspections of data indicated that relationships between cost and output in the production of FAA ATC services were linear.

2.2 Group Costs

For each operating site, several alternative specifications of the output terms were tested. The objective was to determine whether or not there were identifiable differences in the costs of producing services for different user groups. Standard analysis of variance techniques were applied to the coefficients for each cost function tested. The results are discussed for each operating site immediately below.

2.3 Multicollinearity

Many approaches have been employed in the statistical literature to detect multicollinearity. When multicollinearity is present, it is difficult to disentangle the unique effects of each predictor on the responsible variable. As a result,

regression coefficients become unstable and their values may be subject to dramatic changes due to additions or deletions of variables, or small changes in datasets. One would expect that multicollinearity could be a problem for cross-sectional cost functions such as those estimated for this study. For example, FSSs which produce large numbers of pilot briefs, also are likely to take a large number of flight plans; the opposite would be true at smaller facilities.

In order to detect the seriousness of such problems, the following factors were evaluated:

- o High correlation between two or more explanatory variables.
- o High R-squared value with low partial correlation coefficients.
- o A high condition index with high variance-decomposition proportions for two or more estimated regression coefficient variances.[4]

The results for the test conducted for each type of ATC site are reported in the sections immediately below. The discussion now turns to the results of the regression experiments.

2.4 ARTCCs

A comparison of the average values of variables included in the cost functions are shown in Table 2.2.

Table 2.2

MEAN VALUES OF ARTCC VARIABLES

22 Observations

Mean Values	1984	1992
Total Cost	$22,722,500 (1984 - $)	$36,825,200 (1986 - $)
Air Carrier Handles	682,507	884,248
Commuter Handles	115,816	201,916
GA Handles	416,190	568,957
Military Handles	220,354	218,364

It is interesting that the average number of military handles at an ARTCC is forecast to decline in the period 1984 to 1992. In contrast, there are sharp increases in commuter handles, and somewhat smaller increases forecast for air carrier and general aviation handles. The table also indicates that air carriers account for nearly 50 percent of the activity at ARTCCs.

The results of the regression experiments for 1984 and 1992 are shown in Tables 2.3 and 2.4. In general, both estimated cost functions appear to be sound statistically. The individual coefficients have the expected signs, and are highly significant. In addition, both models explain almost 90 percent of the variation in costs.

Table 2.5 reports the results of the tests of the properties of the ARTCC cost functions. Evaluations of both the log linear and quadratic forms resulted in increased collinearity in the

Table 2.3

1984 ARTCC

Commuter	$ 13.93	3.83
GA	$ 12.63	4.31
Military	$ 21.30	4.55

Joint Cost per Site = $ 4,082,285

R-Square = 0.896

Activity Measure: Handles

Cost Measure: AFS and ATC Labor and Leased Telecommunications

Table 2.4

1992 ARTCC

Econometric Results

User Group	($-1986) Estimated MC	t-Statistics
Air Carrier	$ 10.86	10.47
Commuter	$ 10.86	10.47
GA	$ 10.86	10.47
Military	$ 17.29	4.12

Joint Cost per Site = $ 5,865,511

R-Square = 0.872

Activity Measure: Handles

Cost Measure: AFS and ATC Labor

dataset. Visual inspection of the data indicated that a linear relationship existed between ARTCC costs and output.

Table 2.5

TESTS OF PROPERTIES OF ARTCC COST FUNCTIONS

Test	Result
Non-Linearity	Negative--Collinearity; visual inspection showed linear relationship
User Group Costs	Three separate groups identified: AC/COM, GA & MIL in 1984. Two groups identified in 1992: military, all others
Collinearity	Negative--no indications under alternative tests

Analysis of variance tests indicated that three separate cost groups could be identified for the 1984 regression. Air carriers and commuters exhibited similar cost properties at ARTCCs. These were distinct from general aviation and military users, with the former exhibiting lower costs than air carriers and commuters, and the military exhibiting significantly higher costs. In the 1992 results, only two separate groups were identified: the military, and all other user groups. Again, the military marginal costs were higher than those of other user groups. This result probably reflects the increased costs imposed on ARTCCs by military users operating in Special Use Airspace. Not only must controllers pay strict attention to the military operators, but civilian operators must be guided around these geographic areas during military exercises.

Finally, none of the alternative tests for multicollinearity indicated any problem for either of the ARTCC cost functions.

2.5 FSSs

Table 2.6 reports the mean values of the variables used in the FSS cost equations.

Table 2.6

MEAN VALUES OF FSS VARIABLES

306 Observations in 1984; 59 Observations in 1992

Mean Values	1984	1992
Total Cost	$769,899 (1984 - $)	$3,197,325 (1986 - $)
Pilot Briefs	50,043	315,762
IFR Flight Plans	21,167	139,360
VFR Flight Plans	6,312	37,403
Air Contacts	27,919	144,757

What is immediately obvious from the table is the vast differences between the average facilities in 1984 and 1992. Both cost and output measures are substantially larger for the 1992 advanced FSS system, than for the current system. This is wholly due to the expected reduction in the number of FSS stations from 306 in 1984 sample to 59 in 1992 sample. It should also be noted that the results for different user groups are not reported in Table 2.6. This is due to the finding that there were no differences found in the cost of producing FSS services for different user groups.

The results of the regression experiments for FSSs in 1984 and 1992 are reported in Tables 2.7 and 2.8 respectively. In general, both estimated cost functions appear to be statistically sound, with individual coefficients having expected signs and high significance. Both models explain approximately 90 percent of the variation in FSS costs.

Shown in Table 2.9 are the results of the tests of properties of the FSS cost functions. Tests for non-linearity proved to be negative, with both the log linear and quadratic forms having less desirable properties than the linear form.

Table 2.9

TESTS OF PROPERTIES OF FSS COST FUNCTIONS

Test	Result
Non-Linearity	Negative--Collinearity; visual inspection showed linear relationship
User Group Costs	No difference--separate user group specifications showed similar marginal costs
Cost of Services	Positive in current system, no difference in future
Collinearity	Positive in 1984--IFR flight plans and pilot briefs: specified together; air contacts and VFR flight plans: alternatives inconsistent with time and motion study

Analysis of variance tests indicated that there were no differences in the cost of producing FSS services for different user groups. However, some differences were found in the cost of

Table 2.7

1984 FSS

Econometric Results

Type of Service	($-1984) Estimated MC	t-Statistics
Pilot Briefs	$ 6.86	44.96

Table 2.8

1992 FSS-ALL SERVICES

Econometric Results

User Group	($-1986) Estimated MC	t-Statistics
Pilot Briefs	$ 4.27	3.67
IFR Flight Plans	$ 4.27	3.67
VFR Flight Plans	$ 4.27	3.67
Air Contacts	$ 4.27	3.67

Joint Cost per Site = $ 477,317

R-Square = 0.897

Activity Measure: Pilot Briets + VFR and IFR Flight Plans + Air Contacts

Cost Measure: AFS and ATC Labor

producing individual services in 1984. Here, distinct costs can be identified for air contacts, pilot briefs and IFR flight plans together, and VFR flight plans. No differences in the cost of producing services were found for the 1992 cost function.

Finally, multicollinearity was detected in the 1984 regression experiments. Specifically, IFR flight plans and pilot briefs were found to be collinear; to remedy the problem, these variables were added together, and specified as a single variable in the regression experiment. In addition, some collinearity existed between air contacts and VFR flight plans. Several alternative specifications of the cost function were estimated to attempt to reconcile this problem. However, the alternatives were inconsistent with a time-and-motion study for the production of FSS services.[5] Specifically, VFR flight plans command approximately 2.5 times more of a FSS specialist's time than an air contact. For this reason, specifications shown in Table 2.7 was deemed to be more reliable than the alternatives evaluated.

2.6 TRACONs

Shown in Table 2.10 are the mean values of the variables used in the TRACON regressions for 1984 and 1992. The output measures reported in this table are termed TSOs which include operations, seconds and overs at towers equipped with radar facilities. Several things are of note in the table. First, total TSOs are dominated by general aviation users. Second, military activity at TRACONs are forecast to remain constant in

the period 1984 through 1992. Third, general aviation users are forecast to increase their activity at TSOs faster than other groups in that same time period.

Table 2.10

MEAN VALUES OF TRACON VARIABLES

185 Observations

Mean Values	1984	1992
Total Cost	$2,745,123 (1984 - $)	$3,696,970 (1986 - $)
Air Carrier TSOs	60,432	66,237
Community TSOs	31,967	35,950
GA TSOs	126,951	178,314
Military TSOs	21,494	20,805

The results of the regressions for 1984 and 1992 are shown in Tables 2.11 and 2.12 respectively. Both estimated cost functions appear to be sound statistically. The individual coefficients have the expected sign and are highly significant. The 1984 model explains over 85 percent of the variation in cost while the 1992 model explains over 80 percent.

Shown in Table 2.13 are the results of tests of the properties of the TRACON cost functions.

Table 2.11

1984 TRACON

Econometric Results

User Group	($-1984) Estimated MC	t-Statistics
Air Carriers	$ 12.80	28.38
Commuters	$ 12.80	28.38
GA	$ 3.44	4.18
Military	$ 12.80	28.38

Joint Cost per Site = $ 850,312

R-Square = 0.867

Activity Measures: Operations + Seconds + Overs

Cost Measures: AFS and ATC Labor and Leased Telecommunications

Table 2.12

1992 TRACON

Econometric Results

User Group	($-1986) Estimated MC	t-Statistics
Air Carriers	$ 12.55	23.83
Commuters	$ 12.55	23.83
GA	$ 4.72	5.14
Military	$ 12.55	23.83

Joint Cost per Site = $ 1,308,847

R-Square = 0.804

Activity Measure: Operations + Seconds + Overs

Cost Measure: AFS and ATC Labor

Table 2.13

TESTS OF PROPERTIES OF TRACON COST FUNCTIONS

Test	Result
Non-Linearity	Negative--Collinearity; Visual inspection showed linear relationship
Cost of Services	No difference in producing operations, second and overs
User Group Costs	GA costs different--separate specifications showed all other user groups the same
Collinearity	Negative--no indications under alternative tests

Tests for non-linearity proved to be negative due to increases in collinearity in the dataset. Analysis of variance tests were run to determine whether there were differences in the costs of producing operations, seconds and overs at TRACONs. The results indicated that the costs closely corresponded to one another which resulted in a specification of the cost function with an activity variable that included all three types of services provided at TRACONs.

The analysis of variance tests for the cost of producing services for different user groups indicated that there were two distinct groups of users in both 1984 and 1992: general aviation users, and all other users. The general aviation users exhibited substantially lower costs per TSO than did other groups. It is surmised that this result reflects the lower weight assigned to general aviation operations in both FAA Staffing Standards and FAA Establishment Criteria.

Finally, none of the tests for multicollinearity indicated any problem with either of the TRACON cost functions.

2.7 Towers

Table 2.14 summarizes the mean values of the variables used in the 1984 and 1992 tower regression experiments. The most

Table 2.14

MEAN VALUES OF TOWER VARIABLES

203 Observations

Mean Values	1984	1992
Total Cost	$551,260 (1984 - $)	$626,926 (1986 - $)
Air Carrier Operations	1,281	1,772
Commuter Operations	5,733	8,605
GA Operations	110,869	154,439
Military Operations	4,106	4,442
Percent Level One Facilities	43%	43%

striking feature of this table is the dominance of general aviation operators at FAA towers without radar. This dominance is expected to continue in 1992. As part of the regression analysis, two types of towers were identified: level one and all other towers. Approximately 43 percent of the towers in both 1984 and 1992 were identified as level one facilities.

The results of the regression experiments for 1984 and 1992 are shown in Tables 2.15 and 2.16 respectively. Both cost functions appear to be sound statistically. The coefficients for commuter operators exhibit higher standard errors than for other types of operators, but analysis of variance test indicate significance. These results are also somewhat less robust than other types of operating sites. In part this is due to the fact that the joint costs at each site are a high proportion of the total costs.

Shown in Table 2.17 are the results of tests of the properties of the tower cost functions.

Table 2.17

TESTS OF PROPERTIES OF TOWER COST FUNCTIONS

Test	Result
Non-Linearity	Negative--Collinearity; visual inspection showed linear relationship
User Group Costs	Four separate groups--AC, COM, GA, MIL
Collinearity	Negative--no indications under alternative tests

Alternative functional forms were tested (including the log linear and quadratic forms) but the results indicated that the linear cost function had superior results. Four separate user groups were identified in both 1984 and 1992: air carriers, general aviation, commuters and the military. Neither of the equations reported showed any indications of multicollinearity.

Commuters	$ 1.75	2.86
GA	$ 1.16	10.04
Military	$ 3.05	3.08
Level 1	-$252,713	11.16

Joint Cost per Site = $ 519,151

R-Square = 0.763

Activity Measure: Operations

Cost Measure: AFS and ATC Labor

Finally, level one facilities exhibited substantially lower costs than did other FAA towers. In 1984, the average level one facility exhibited costs $85,000 lower than other towers, while in 1992, the reduction in costs is expected to be $253,000. The coefficient on the dummy variable for level one facilities is subtracted from the constant term in the equation to reconcile these cost differences.

2.8 Conclusions

Perhaps the most important conclusion to be drawn is that robust econometric results can be developed to explain the variance in cost of producing air traffic control services at FAA operating sites. These cost functions are linear; changes in activity levels within the range of the datasets employed would not substantially alter the marginal costs of production. As a result, the marginal costs can be used directly to derive estimates of avoidable costs, and also can be confidently used in the Ramsey Pricing algorithms employed to allocate joint costs in this study.

NOTES

[1]In the future specifications, FSS services were added together only because the analysis of variance test indicated that there were no differences in the cost of producing future services.

[2]The distinction between users is suppressed in this presentation to improve clarity.

[3]It should be noted that the 1984 marginal costs for FSS services are reported as being equal for all FSS output. The reported results in Table 2.1 are weighted averages. The actual marginal costs reported below are different for the different FSS services for 1984. This was not the case for 1992, however.

APPENDIX A

DATA FOR 1984 AND 1992 CALCULATIONS

This appendix describes the derivation of activity data used in the cost functions previously described. The database employed in the regression studies is also included in the appendix. A glossary of variable names preceeds the database.

TRACON and Tower Databases

The 1984 databases for TRACONs and Towers were modified to reflect actual activity exhibited by air carriers and commuters. FAA activity counts do not separately identify commuter operations.

OAG Data

The tapes for the North American Edition of the Official Airline Guide were run for the period October 1984 through September 1985. For each airport in North America, the total number of the following scheduled flights were counted:

- domestic flights by U.S. carriers,
- domestic flights by international carriers,
- domestic flights by U.S. commuter airlines (defined aircraft with fewer than 60 seats),
- domestic flights by international commuter airlines,
- international flights by U.S. carriers,
- international flights by international carriers,
- international flights by U.S. commuters,
- international flights by international commuters.

Adjustments to OAG Data

OAG and FAA official operations counts do not agree for the following reasons.

- o FAA counts do not explicitly identify commuter air carriers. Air taxis and commuter airlines are both found in the air taxi counts made by the FAA; in addition, some commuter flights are included in FAA counts of air carrier operations.
- o OAG data reflect scheduled operations. Not all scheduled flights actually take place.
- o FAA counts include charter and freight operations while OAG data do not. Form 41 data indicate that TRACONs and towers average only five freight operations per day.

The OAG data were reconciled to the FAA official counts since the latter represent the actual activity which took place at each Tower and TRACON in 1984. The following adjustments were made.

Since not all scheduled flights actually take place, a completion ratio of 0.985 was applied to all OAG flights. This is the average Form 41 completion rate for 1984.

The next set of adjustments were made at the site specific level. There are four relevant activity counts available at each Tower and TRACON:

- o FAA Air Carrier,
- o FAA Air Taxi,
- o OAG Air Carrier,
- o OAG Commuter.

The adjustments made depended on the relative sizes of the counts. The four possibilities and the adjustments made are shown in Figure 1. Each cell in the matrix is numbered:

- Cell 1: Both FAA air carrier and air taxi counts exceed the OAG counts. This indicates that some commuter operations are counted in the FAA air carrier operations counts and in the FAA air taxi counts. Therefore, the OAG figures are probably more accurate and are used for air carrier and commuter operations. The air taxi counts then become a residual as illustrated in the figure.
- Cell 2: FAA air carrier counts exceed OAG air carrier counts but OAG commuter counts exceed FAA air taxi counts. FAA air carrier counts include commuter operations and therefore the OAG air carrier counts are likely to be more accurate than those made by the FAA. Two further adjustments are possible. First, if the remaining FAA operations exceed the OAG commuter counts, then air taxi and commuter operations exist at the airport; therefore, commuter operations are assumed to be equal to the OAG counts. The residual then becomes the air taxi count. Otherwise, there are unlikely to be a significant number of air taxi operations at the airport, and commuters are allocated all remaining FAA air carrier and FAA air taxi operations.

Figure 1

ADJUSTMENTS TO SITE SPECIFIC ACTIVITY DATA

Air Carrier	FAA Air Taxi > OAG Commuter	FAA Air Taxi < OAG Commuter
FAA > OAG	1.) AC = OAGAC COM = OAGCM AT = (FAAAC + FAAT - OAGAC - OAGCM)	2.) Let X = FAAC + FAAAT - OAGAC AC = OAGAC If: X ≥ OAGCM then COM = OAGCM AT = X - COM Otherwise: COM = X AT = 0
FAA < OAG	3.) AC = FAAAC COM = OAGCM AT = FAAAT - COM	4.) AC = FAAC COM = FAAAT AT = 0

Legend:
AC = Air Carrier
FAAAC = FAA Air Carrier Operations
OAGAC = OAG Air Carrier Flights
COM = Commuter
OAGCM = OAG Commuter Flights
AT = Air Taxi
FAAAT = FAA Air Taxi Operations

- o Cell 3: OAG air carrier counts exceed FAA air carrier counts, but FAA air taxi counts exceed OAG commuter counts. Fewer OAG air carrier operations were completed than would be expected from the Form 41 completion rate. Therefore, the air carrier operations counted by the FAA are assumed to be correct. Because the FAA air taxi counts exceed the OAG commuter operations, there are probably significant numbers of commuter and air taxi operations. Therefore, commuter operations are assumed equal to the OAG commuter counts, with the residual being assigned to the air taxi category.
- o Cell 4: Both the OAG air carrier and commuter counts exceed the FAA counts. Both air carriers and commuters appear to complete fewer operations than would be expected from Form 41 completion rate data. Therefore, FAA air carrier and air taxi operations counts are used to represent flights made by air carriers and commuters. Air taxi operations are assumed to be zero.

This allocation process results in a reassignment of most air taxi and some air carrier operations to commuter airlines. While the process is not perfect, it should be more representative of the actual operations taking place at Towers and TRACONs.

The final adjustment made to the data was to allocate all remaining air taxi operations at each site to general aviation. At each site, four types of operations data were available:

- o Air Carrier Operations,
- o Commuter Operations,
- o General Aviation Operations (including air taxis),
- o Military Operations.

These operations data were then used in conjunction with site-specific cost data to estimate the marginal costs of FAA production.

ARTCC and FSS Databases

Activity counts for these facilities were modified to separately identify commuter operators based on the results for TRACONs and towers. Commuters were assumed to account for a proportionate share of air carrier activity at these facilities with one exception--they were assumed to account for zero overs at ARTCC's because of their relatively short stage lengths. These overs were assumed to remain the responsibility of other air carriers.

GLOSSARY

ACNEW	=	Estimated Air Carrier Operations
COM	=	Estimated Commuter Operations
GANEW	=	Estimated General Aviation Operations
GATSO	=	Estimated Total General Aviation Operation Plus
HANDL	=	Overs + 2* Departures
LEVEL 1	=	Tower Type Indicator
MILTDT	=	Total Military Operations
NOTGA	=	Estimated Total of Non-General Aviation Operations Plus Secondaries Plus Overs
NOTMI	=	Estimated Non-Military Handles
QIFRPB	=	IFR Flight Plans + Pilot Briefs
TACT	=	Total of Contacts, Flight Plans and Briefs
TQAC	=	Total Contacts
VFRFLT1	=	VFR Flight Plans
